

Progressive Fundraising — Card Vault Merchant Workflows

How each merchant's cards move from source file to customer-ready output

Prepared by Redstamp — July 2026

01 Overview — one vault, one workflow

Every merchant's cards follow the same path. Source files arrive in different shapes, but import and validation normalize each one into a single canonical card record inside the Secure Card Vault. From there, per-order output rules decide how each fulfillment request is packaged for the customer.

MODE A Repackage — the vault exports the stored credentials (URLs, codes, PINs) as a password-protected Excel file.

MODE B Generate — the vault renders a PDF card per credential and bundles them in a password-protected ZIP.

Because every merchant flows through this same spine, adding a new merchant that fits an existing credential pattern is a configuration and end-to-end validation task — not new software.

The customer-ready file is an internal fulfillment file: Progressive downloads it from the vault and delivers it to the customer through your existing process. Exact export layouts are validated against Progressive's known-good example files and confirmed together at kickoff.

02 URL + Challenge Code — CashStar merchants

Tim Hortons · Best Buy · Sephora · DoorDash · Earls · The Keg · other CashStar-delivered brands

All CashStar-delivered brands arrive the same way: a links file with one row per card, carrying a redemption URL and a challenge code. One import mapping covers the whole family.

Why this matters: every additional CashStar brand reuses this exact pipeline — new brands are onboarded by configuring the mapping and validating one file end-to-end.

03 URL only — Reference-Id merchants

Fairmont · Winners

The simplest pattern: each card is a single redemption URL. The workflow spine is identical to CashStar — there is just one credential field to map, store, and repackage.

04 URL + Account # + PIN — PC / Loblaws allocation

Loblaws · Shoppers Drug Mart · sibling banners under the same parent

The PC / Loblaws family carries three credential fields per card: a redemption URL, an account number, and a PIN. Because every sibling banner under the parent uses the same file format, one import mapping covers all of them.

Credential shape: **Redemption URL + account # + PIN**

Output: **Mode A — Repackage**

One mapping, many banners: sibling banners under one parent share one file format, so onboarding another banner in this family is a configuration check, not a new integration.

05 Card # + PIN — Code-and-PIN merchants

Cara brands · Chapters-Indigo

These merchants supply a card number and PIN per card — no redemption URL. The vault stores both fields on the canonical card record and repackages them at fulfillment.

Output format is an order-level rule, not fixed per merchant. Chapters-Indigo orders, for example, can also be output as generated PDF cards (Mode B) when the order calls for it — the same vault records feed either output.

06 Claim Code → Generated PDF — Amazon

Amazon

Amazon supplies claim codes rather than finished cards. The vault stores each claim code as a canonical card record, and at fulfillment it generates a rendered PDF card for every allocated code — Mode B end to end.

Generation happens at fulfillment, not at import — the vault holds only the claim code until an order needs it, then produces the finished PDF cards for that specific fulfillment request.

07 On-Demand Activation — Walmart

Walmart — the one two-way flow

Walmart is the exception: there is no pre-purchased inventory sitting in the vault. When a paid order arrives, the vault prepares an activation work file, a Progressive team member runs the activation externally with Walmart / Fiserv, and the activated live cards come back into the vault to be allocated and packaged like any other merchant.

Credential shape: **Activated live card (on demand)**

Flow: **Two-way — out for activation, back for fulfillment**

The round trip is the only difference. Once activated cards are back in the vault, Walmart fulfillment uses the same allocation and output steps as every other merchant — including combining Walmart cards with other merchants' cards in a single customer-ready file.
